KUBERNETES STORAGE CHALLENGES

Storage challenges

- Kubernetes is a platform to manage distributed apps
  - Traditionally stateless
- Reliance on external storage (outside Kubernetes)
  - Not portable if the environment changes
  - Deployment burden
  - Day 2 operations (add capacity etc) - who is managing the storage?
- Reliance on cloud provider managed services
  - Vendor lock-in

ROOK

What is Rook-Ceph?

- Open Source
- Storage Operator for Kubernetes
- Automates Management of Ceph
  - Deployment
  - Configuration
  - Upgrading
- CNCF Graduated project (Oct 2020)
- Storage is then provided from the Kubernetes cluster
- Offers homogeneous experience regardless of the platform

CEPH

What is Ceph?

- Open Source
- Distributed storage software-defined solution
  - Block (Kernel module / QEMU plugin / NBD)
  - Shared File System (Native driver / FUSE)
  - Object Storage (Amazon S3 compliant)
- Support snapshot/clone/geo-replication for all storage interfaces
- Robust and battle tested for +10 years

ROOK-CEPH ARCHITECTURE

Architectural Layers

- Rook:
  - The operator owns the management of Ceph
- Ceph-CSI:
  - CSI driver dynamically provisions and connects client pods to the storage
- Ceph-COSI: coming soon! Just like CSI but for Object Bucket Claims
- Ceph:
  - **Data** layer

Dynamic provisioning

NETWORKING IN CEPH

Network capability

- Ceph supports two networks:
  - public (client-side)
  - cluster replication
- Ceph functions with a public network only, but you may see significant performance improvement with a second “cluster” network

Network topology

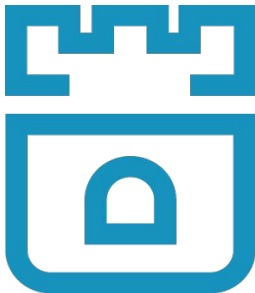
NETWORKING WITH MULTUS IN ROOK-CEPH

Networking models

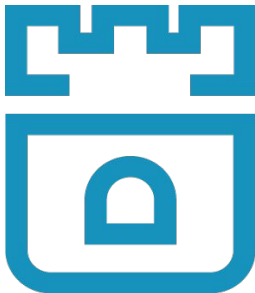
- Rook supports the following networking methods:
  - Traditional pod networking - single network interface - default SDN
  - Host networking - runs on host network namespace and uses host IP. All host's network stack is visible
  - Multus - Rook supports addition of public and cluster network for Ceph



IPAM - choose wisely

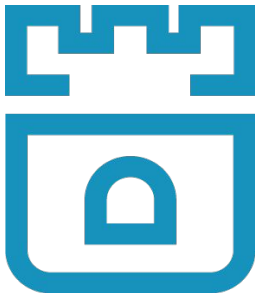
All of our testing and recommandations go with the *'whereabout'* IP Address Management:

- Cluster-wide IP assigning support
- IPv4 and IPv6 support (not dual-stack)
- No DHCP involved!



Network Attachment Definition

```yaml
apiVersion: "k8s.cni.cncf.io/v1"
kind: NetworkAttachmentDefinition
metadata:
  name: rook-public-nw
spec:
  config: '{
      "cniVersion": "0.3.1",
      "name": "public-nad",
      "type": "macvlan",
      "master": "ens5",
      "mode": "bridge",
      "ipam": {
        "type": "whereabouts",
        "range": "192.168.1.0/24"
      }
    }'
```



ROOK-CEPH CRD

```yaml
apiVersion: ceph.rook.io/v1
kind: CephCluster
metadata:
  name: rook-ceph
  namespace: rook-ceph
spec:
  ...
  ...
  network:
    provider: multus
    selectors:
      public: rook-ceph/rook-public-nw
      cluster: rook-ceph/rook-cluster-nw
```

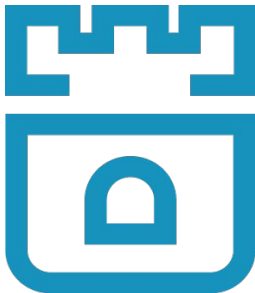
PERFORMANCE

What's in the box?

The hardware used is not relevant. We are simply focusing on comparing with and without multiple network interfaces.

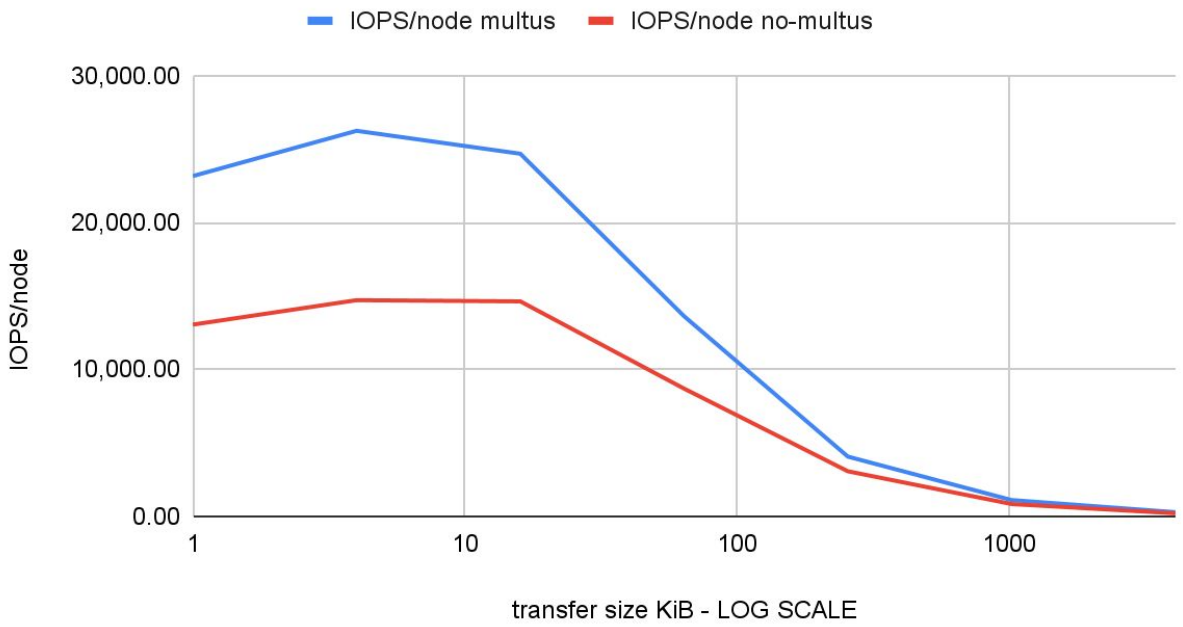
Networks:

1. Default SDN network
2. Ceph public network (multus)
3. Ceph private network (multus)

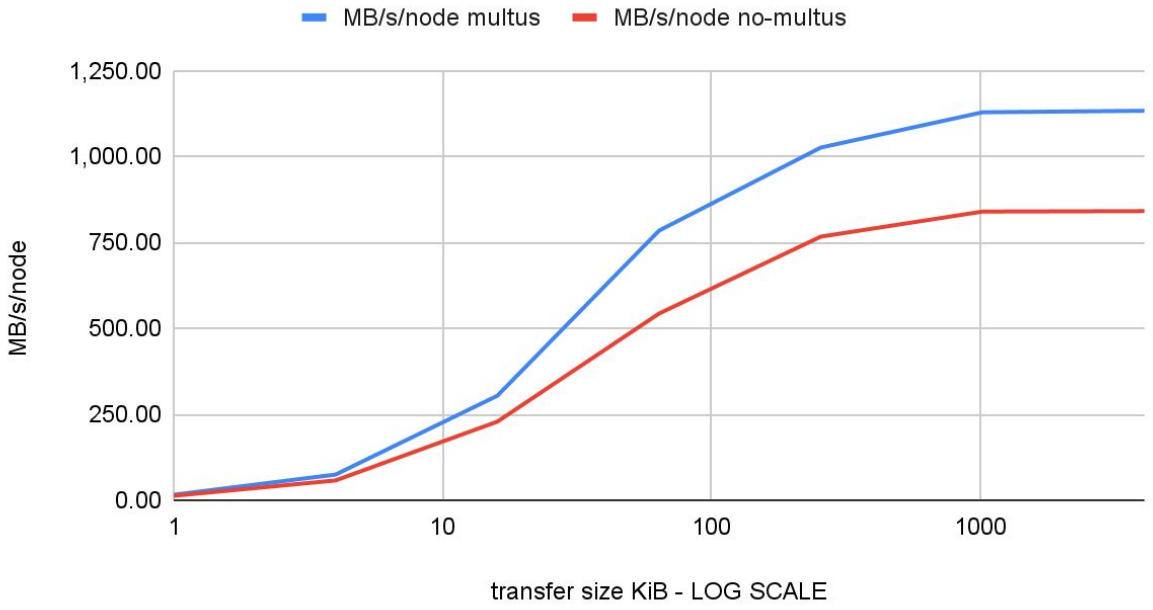


Random WRITE - IOPS and Bandwidth

randwrite IOPS/node - with and without multus

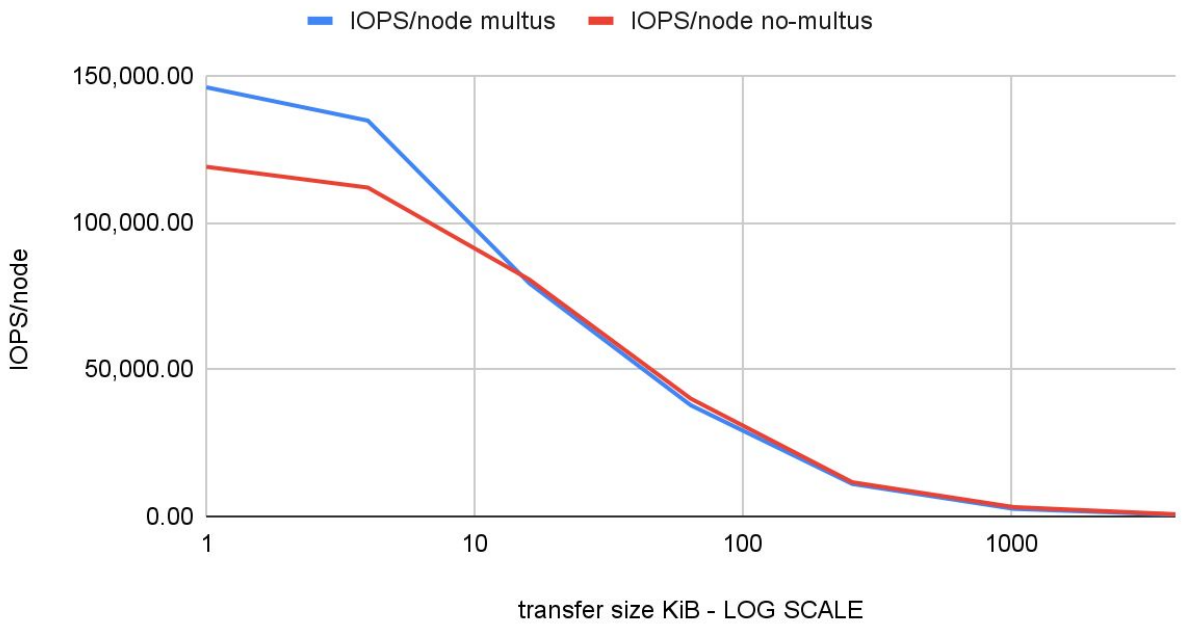


randwrite MB/s/node - with and without multus



Random READ - IOPS and Bandwidth

randread IOPS/node - with and without multus



randread MB/s/node - with and without multus

20% %deviation for multus 4096KiB

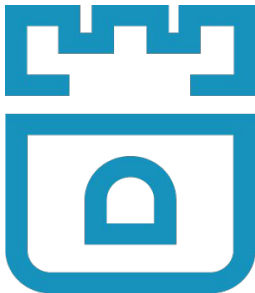
KEY TAKEAWAYS

Wrap it up

- Separating Ceph networks is possible with Multus
- Whereabout IPAM is preferred
- Performance improvement than just using a single interface
- Available since Rook v1.7



Thanks!
